Theoretical bound

- Given N elements in the set
- Spend k bits per element
- Get a false positive rate of $1/2^k$

Usual constraints

- Fixed initial capacity
- Difficult to update safely without access to the set
- To get a 1% false-positive rate: ≈ 8 bits?

Conventional Bloom filter

- Start with a bitset B .
- Using k hash functions f_1, f_2, \dots

Checking an element: implementation

- Typical implementation is *branchy*
- If not $(B[f_1(x)] = 1)$, return false
- If not $(B[f_2(x)] = 1)$, return false
- ...
- return true

```
uint64_t hash = hasher(key);
uint64_t a = (hash >> 32) | (hash << 32);
uint64_t b = hash;
for (int i = 0; i < k; i++) {
    if ((data[reduce(a, length)] & getBit(a)) == 0) {
        return NotFound;
    }
    a += b;
}
return Found;
```

Bloom filters: upsides

- Fast construction
- Flexible: excess capacity translates into lower false positive rate
- Degrades smoothly to a useless but 'correct' filter

Bloom filters: downsides

- 44% above the theoretical minimum in storage
- Slower than alternatives (lots of memory accesses)

Memory accesses

number of hash functions	cache misses (miss)	cache misses (hit)
8	3.5	7.5
11	3.8	10.5

(Intel Ice Lake processor, out-of-cache filter)

Mispredicted branches

number of hash functions	all out	all in
8	0.95	0.0
11	0.95	0.0

(Intel Ice Lake processor, out-of-cache filter)

Performance

number of hash functions	always out (cycles/entry)	always in (cycles/entry)
8	135	170
11	140	230

(Intel Ice Lake processor, out-of-cache filter)

Blocked Bloom filters

- Same as a Bloom filters, but for a given object, put all bits in one cache line
- Optional: Use SIMD instructions to reduce instruction count

Blocked Bloom filters: pros/cons

- Stupidly fast in both construction and queries
- ~56% above the theoretical minimum in storage

```
auto hash = hasher_(key);  
uint32_t bucket_idx = reduce(rotl64(hash, 32), bucketCount);  
__m256i mask = MakeMask(hash);  
__m256i bucket = directory[bucket_idx];  
return _mm256_testc_si256(bucket, mask);
```

Binary fuse filters

- Based on theoretical work by Dietzfelbinger and Walzer
- Immutable datastructure: build it once
- Fill it to capacity
- Fast construction
- Fast and simple queries

Arity : 3-wise, 4-wise

- 3-wise version has three hits, 12% overhead
- 4-wise version has four hits, 8% overhead

Queries are silly

- Have an array of *fingerprints* (e.g., 8-bit words)
- Compute 3 (or 4) hash functions: $f_1(x)$, $f_2(x)$, $f_3(x)$
- Compute fingerprint function ($f(x) \rightarrow$ 8-bit word)
- Compute XOR and compare with fingerprint:
$$(B[f_1(x)] = 1) \text{ XOR } (B[f_2(x)] = 1) \text{ XOR } (B[f_3(x)] = 1) = f(x)$$

```
bool contain(uint64_t key, const binary_fuse_t *filter) {  
    uint64_t hash = mix_split(key, filter->Seed);  
    uint8_t f = fingerprint(hash);  
    binary_hashes_t hashes = hash_batch(hash, filter);  
    f ^= filter->Fingerprints[hashes.h0] ^ filter->Fingerprints[hashes.h1] ^  
        filter->Fingerprints[hashes.h2];  
    return f == 0;  
}
```

	cache misses	mispredictions
3-wise binary fuse	2.8	0.0
4-wise binary fuse	3.7	0.0

(Intel Ice Lake processor, out-of-cache filter)

	always out (cycles/entry)	always in (cycles/entry)	bits per entry
Bloom $k = 8$	135	170	12
3-wise bin. fuse	85	85	9.0
4-wise bin. fuse	100	100	8.6

(Intel Ice Lake processor, out-of-cache filter)

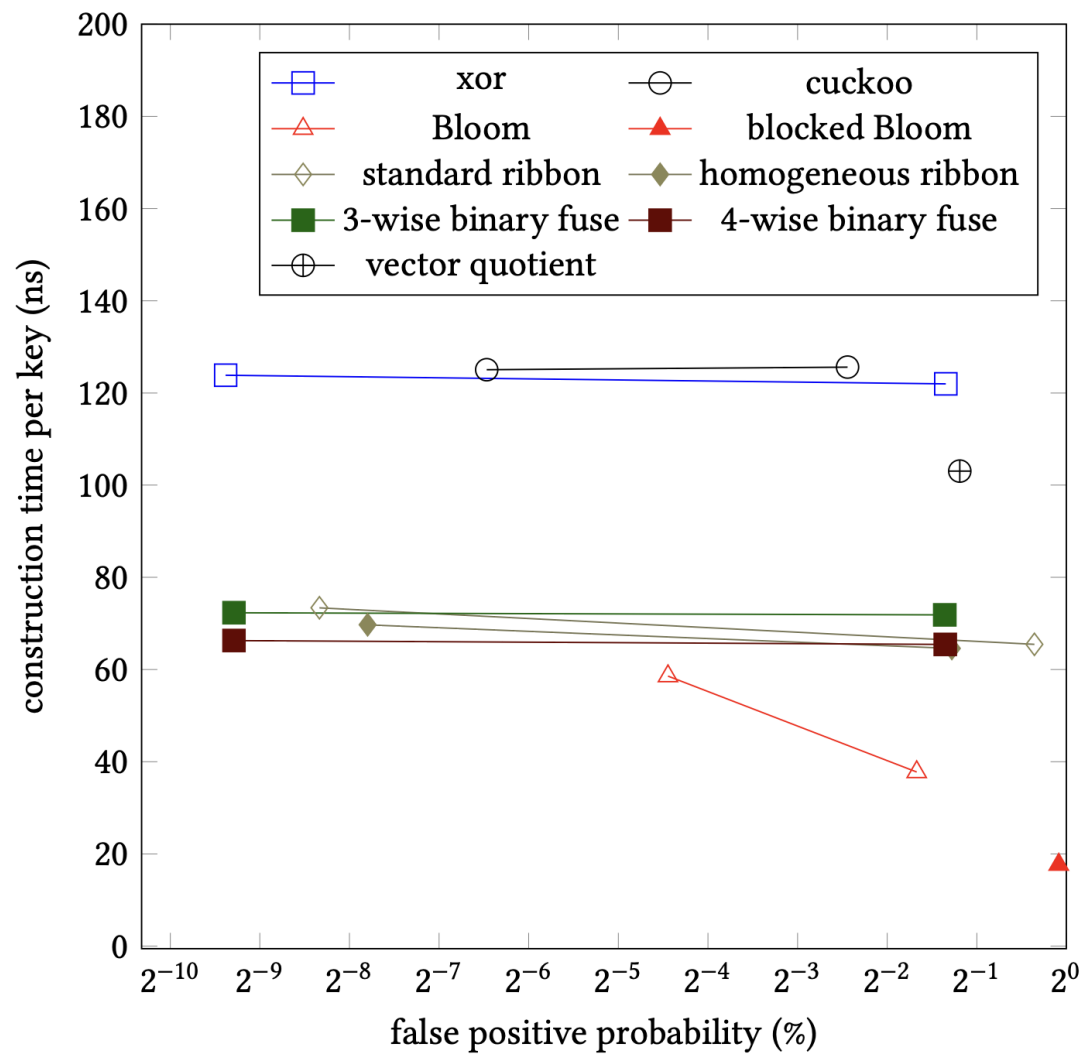

(a) Relative space usage

(b) Query time

Construction: Performance

- Implemented naively: terrible performance (random access!!!)
- Before the construction begins, sort the elements of the sets according to the segments they are mapped to.
- This greatly accelerates the construction

How does the performance scale with size?

For warm small filters, number of access is less important.
Becomes more computational.

For large cold filters, accesses are costly.

10M entries

	ns/query (all out)	ns/query (all in)	fpp	bits per entry
Bloom	17	14	0.32%	12.0
Blocked Bloom (NEON)	3.8	3.8	0.6%	12.8
3-wise bin. fuse	3.5	3.5	0.39%	9.0
4-wise bin. fuse	4.0	4.0	0.39%	8.6

(Apple M2)

100M entries

	ns/query (all out)	ns/query (all in)	fpp	bits per entry
Bloom	38	33	0.32%	12.0
Blocked Bloom (NEON)	11	11	0.6%	12.8
4-wise bin. fuse	17	17	0.39%	9.0
4-wise bin. fuse	20	20	0.39%	8.6

(Apple M2)

Compressibility (zstd)

	bits per entry (raw)	bits per entry (zstd)
Bloom $k = 8$	12.0	12.0
3-wise bin. fuse	9.0	8.59
4-wise bin. fuse	8.60	8.39
theory	8.0	8.0
